Pitch Deck Assembly

ParcelCare: exception resolution for warehouses serving SMEs

ParcelCare uses AI to handle warehouse exceptions based on the action needed. It automates routine communication and follow-ups after a separate checker validates the response, while cases requiring physical verification go to warehouse staff. This brief presents the problem, market evidence, solution and proposed business model.

01 The Problem

Warehouses serving multiple SMEs handle quantity discrepancies, damaged goods, picking errors and delivery failures. Teams often coordinate these cases through separate messages and manual checks. Evidence becomes difficult to follow, ownership stays unclear and SMEs repeatedly ask for updates. [1]

Illustrative scenarios: a delayed delivery requires a checked courier update, an SME notification and a follow-up. When 100 items are expected but only 90 arrive, the 10-item shortage requires a recount and a dispatch-record check. Each exception needs a different next action.

Business consequence: repeated investigation consumes staff time and delays decisions. The frequency, cost and resolution time of these problems still need measurement in a customer pilot.

02 Market Research

Published evidence: DHL's 2025 Business Edition surveyed 4,050 e-commerce businesses across Europe, the Americas and Asia Pacific. It reports that 96% of retailers consider their logistics offering important to securing sales. This supports the relevance of logistics service quality, but does not measure demand for ParcelCare or establish a local market size. [2]

Initial customer: warehouse and third-party logistics operators serving several SMEs. The operator is the proposed paying customer; SME representatives and in-house riders participate in relevant workflows. [1, 3]

Positioning hypothesis: chat and spreadsheets coordinate messages, while warehouse systems hold operational records. ParcelCare adds action-based exception handling: checked responses, automated SME updates and follow-ups, and staff handoffs for physical verification. This positioning requires customer and competitor validation.

Research still needed: interview operators and SMEs, measure monthly exception volume and staff time, review existing tools, and test willingness to pay. Estimate the addressable market from qualified warehouses and a validated annual subscription price.

Solution and Business Viability

Action-based AI handling and proposed commercial approach

03 The Solution

ParcelCare's AI handles each warehouse exception according to the action required. Routine communication runs automatically, while physical verification stays with warehouse staff. [4]

Delayed delivery: the AI checks the courier update and validates the response through a separate checker. It then notifies the SME and schedules a follow-up automatically.

Quantity shortage: when 100 items are expected but only 90 arrive, the AI identifies the 10-item shortage and recommends a recount and a dispatch-record check. Warehouse staff perform the physical verification.

Shared case history: evidence, checker responses, notifications and staff decisions support a traceable resolution. AI automates routine communication; staff verify physical facts. ParcelCare complements existing warehouse systems. [1, 4]

04 Business Viability

Revenue model: a proposed monthly subscription per warehouse, with connected SMEs participating in the workflow. Additional warehouse sites, integrations or onboarding support could become paid options after customer validation. Pricing and revenue are not yet validated. [3]

Customer value: automatic SME notifications and follow-ups can reduce repetitive communication, while clear recount and record-check requests help staff focus on physical verification. Estimate staff time value as monthly cases handled multiplied by minutes saved per case and staff cost per minute; validate savings in a pilot.

Cost and profitability: subscription revenue must cover AI usage, hosting, onboarding and support, plus fixed operating and product costs. Break-even customer count equals monthly fixed costs divided by average monthly contribution per paying warehouse, provided that contribution is positive.

Route to market: recruit warehouse pilot partners and test delayed-delivery and shortage workflows. Measure notification time, follow-up completion, staff handling time and resolution accuracy. Test paid conversion and retention before expanding through operator referrals or logistics partnerships.

Viability assessment: commercial viability depends on measured operational value, willingness to pay and sustainable support costs. Customer traction and profitability remain unvalidated.
